

A HEIGHT GAP IN $\mathrm{GL}_d(\overline{\mathbb{Q}})$ AND ALMOST LAWS

LVZHOU CHEN, SEBASTIAN HURTADO AND HOMIN LEE

ABSTRACT. E. Breuillard showed that finite subsets F of matrices in $\mathrm{GL}_d(\overline{\mathbb{Q}})$ generating non-virtually solvable groups have normalized height $\widehat{h}(F) \geq \epsilon_d$, for some positive $\epsilon_d > 0$. The normalized height $\widehat{h}(F)$ is a measure of the arithmetic size of F and this result can be thought of as a non-abelian analog of Lehmer’s Mahler measure problem. We give a new shorter proof of this result. Our key idea relies on the existence of particular word maps in compact Lie groups (known as almost laws) whose image lies close to the identity element.

1. INTRODUCTION

In [6], E. Breuillard proved what can be considered as a non-abelian version of Lehmer’s problem about the Mahler measure of an algebraic number. He showed that if a set $F \subset \mathrm{GL}_d(\overline{\mathbb{Q}})$ of invertible matrices with algebraic entries generates a group that is not virtually solvable, then its arithmetic height (a measure of its arithmetic complexity) is bounded below by an absolute constant $\epsilon_d > 0$ independent of F . Some consequences of Breuillard’s theorem include the existence of a lower bound for the exponential growth of a non-virtually solvable group of $\mathrm{GL}_d(\mathbb{C})$, a strong version of the classical Tits alternative about existence of free subgroups in linear groups, lower bounds in the girth of finite groups of Lie type and very recently some results about the geometry of arithmetic locally symmetric spaces [11]. See [7] for a discussion of some of these applications.

In this article, we will provide a more elementary proof of Breuillard’s theorem that avoids the use of Bilu’s equidistribution theorem [5], results of Zhang [15] about small points on algebraic tori, or results about the geometry of Bruhat–Tits buildings. The key idea in our proof relies on the existence of *word maps* in compact Lie groups whose image lies close to the identity element. These words are known as *almost laws* after Andreas Thom [13]; See Section 2.2.

1.1. Definitions. Let $K \subset \overline{\mathbb{Q}}$ be a number field and let V_K be the set of absolute values on K up to equivalence, which are either archimedean (corresponding to real and complex embeddings of K in \mathbb{R} or \mathbb{C}) or non-archimedean (corresponding to prime ideals in the ring of integers \mathcal{O}_K of K). Let K_v be the corresponding completion of K and define $n_v := [K_v : \mathbb{Q}_p]$, if $v|p$ or $n_v := [K_v : \mathbb{R}]$ if $\mathbb{R} \subseteq K_v$. For a vector $x = (x_1, x_2, \dots, x_d)$ in

K_v^d , we define $\|x\|_v := \max_{i=1}^d |x_i|_v$ if v is non-archimedean and $\|x\|_v := \sqrt{|x_1|_v^2 + \cdots + |x_d|_v^2}$ if v is archimedean.

For a matrix A in $\mathrm{GL}_d(K)$, let $\|A\|_v$ be the operator norm. For a finite set F of matrices in $\mathrm{GL}_d(K)$, let $\|F\|_v := \max_{A \in F} \|A\|_v$. The *height* of F is defined as

$$h(F) := \frac{1}{[K : \mathbb{Q}]} \sum_{v \in V_K} n_v \log^+ \|F\|_v,$$

where $\log^+(x) = \log \max(|x|, 1)$ for a real number x . The *normalized height* is defined by

$$\hat{h}(F) := \lim_{n \rightarrow \infty} \frac{h(F^n)}{n},$$

where F^n consists of all products of n elements in F . The limit above exists because $h(F^n)$ is sub-additive, which also implies $h(F) \geq \hat{h}(F)$.

Our main result is a new proof of the following theorem due to Breuillard [6]:

Theorem 1.1. *For any positive integer d , there exists $\epsilon_d > 0$ such that for any symmetric finite set $F \subset \mathrm{GL}_d(\overline{\mathbb{Q}})$, either*

- (1) *F generates a virtually solvable group, or*
- (2) *$\hat{h}(F) \geq \epsilon_d$.*

Remark 1.2. In section 4 we give a brief discussion on the possible estimates one can get of ϵ_d by using our methods and ideas of E. Breuillard and A. Thom.

Remark 1.3. In [6], Breuillard proved this theorem without the assumption that F is symmetric¹. Moreover he showed that F can be conjugated in such a way that their height and normalized height are comparable by a constant only depending on d . Our proof does not establish these results. Moreover we use the results of Eskin–Mozes–Oh [10] and some lemmas of E. Breuillard [6] that allows us to compare the height and normalized height.

1.2. Idea of the proof of Theorem 1.1. We illustrate the idea of the proof in a very particular case. Assume $d = 2$, $F \subset \mathrm{SL}_2(\overline{\mathbb{Q}})$ and assume that all the entries of elements of F are algebraic integers. In this case, the only contribution to the height comes from archimedean places. Let $w \in \mathbb{F}_2$ be an almost law for $\mathrm{SU}(2)$ (see Section 2.2 for the definition). Suppose for simplicity, there exists $A, B \in F$ such that $\mathrm{Tr}(w(A, B) - Id) \neq 0$ (see Lemma 3.1), and let

$$(1) \quad Q = \prod_{i=1}^k (\mathrm{Tr}(w(A_i, B_i) - Id)),$$

where $k = [K : \mathbb{Q}]$, $A_i = \sigma_i(A)$ and $B_i = \sigma_i(B)$, and $\sigma_i : K \rightarrow \mathbb{C}$ are the different embeddings of K in \mathbb{C} .

¹symmetric means that if $x \in F$, then $x^{-1} \in F$

By construction, Q is a nonzero integer and therefore $|Q| \geq 1$. Let $\delta > 0$ be small enough and let S be the set of i 's such that either $\|A_i\|$ or $\|B_i\|$ is greater than e^δ . There are two cases: If $|S| \geq k/2$, then one of the heights $h(A)$ or $h(B)$ must be greater than $\frac{1}{2}\delta$ and so $h(F) \geq \frac{1}{2}\delta$ and we are done. If $|S| \leq k/2$ we have for $i \notin S$, A_i and B_i are close to a pair of elements of $\mathrm{SU}(2)$ and then for such i 's, $\mathrm{Tr}(w(A_i, B_i) - Id)$ is smaller than say e^{-10} by choosing the almost law appropriately and δ small enough.

Therefore from $|Q| \geq 1$, we obtain

$$\left| \prod_{i \in S} \mathrm{Tr}(w(A_i, B_i) - Id) \right| \geq \left| \prod_{i \notin S} \mathrm{Tr}(w(A_i, B_i) - Id) \right|^{-1} \geq e^{10k/2}$$

and this implies that the height of $w(A, B)$ must be bounded below by a constant $c > 0$ independent of k . Thus $h(F) \geq \frac{1}{|w|} h(F^{|w|}) \geq \frac{1}{|w|} h(w(A, B)) \geq \frac{c}{|w|}$, where $|w|$ is the length of w .

1.3. Organization of the article. In Section 2, we recall definitions and facts about heights, normalized heights, and almost laws. In Section 3, we prove Theorem 1.1. In Section 4 we discuss strategies to obtain explicit estimates about the constant ϵ_d in terms of d .

1.4. Acknowledgements. We would like to thank Emmanuel Breuillard, Michael Larsen, and Andreas Thom for helpful discussions and suggestions. We particularly would like to thank Mikolaj Fraczyk, who noticed the connection between a previous version of our results and the work of Breuillard, and also Vladimir Finkelstein for multiple discussions. HL thanks Michael Larsen for pointing out a mistake in Lemma 3.1 from an early draft and thanks Dylan Thurston for his interest and various discussions.

2. BACKGROUND

In this section, we give detailed definitions and basic properties of the crucial notions in the statements and proofs of our results: *heights* and *almost laws*.

2.1. Heights. For a number field $K \leq \overline{\mathbb{Q}}$ and an absolute value $|\cdot|_v$ on K , define $n_v = [K_v : \mathbb{Q}_p]$ as the degree of the completion K_v of K over the closure \mathbb{Q}_p of \mathbb{Q} in K_v . In the case where ν is archimedean $n_v = 1, 2$ depending on whether ν comes from a real or complex embedding. When ν is non-archimedean, we normalize the absolute value $|\cdot|_v$ on K_v so that its restriction to \mathbb{Q}_p is the standard absolute value, i.e., $|p|_v = 1/p$. With such normalization, we have the following product formula:

Theorem 2.1 (Product formula). *Let K be a number field and V_K be the set of equivalence classes of absolute values on K . Then, for every $x \in K$,*

$$\prod_{v \in V_K} |x|_v^{n_v} = 1.$$

Let k be a local field of characteristic 0. Let $\|\cdot\|_k$ be the standard norm on k^d as in the introduction. We use the same notation for the operator norm on the space $M_d(k)$ of d -by- d matrices with entries in k . Following [6], we define in below the quantities $\Lambda_k(F)$, $E_k(F)$ and $R_k(F)$ for a bounded set $F \subset M_d(k)$.

Definition 2.2. Let F be a bounded subset of matrices in $M_d(k)$. We set

- (1) the *norm* of F as

$$\|F\|_k = \sup_{g \in F} \|g\|_k,$$

- (2) the *minimal norm* of F as

$$E_k(F) = \inf_{x \in \mathrm{GL}_d(\bar{k})} \|xFx^{-1}\|_k,$$

- (3) the *maximal eigenvalue* of F as

$$\Lambda_k(F) = \max\{|\lambda|_k, \lambda \in \mathrm{spec}(q), q \in F\},$$

and

- (4) the *spectral radius* of F as

$$R_k(F) = \lim_{n \rightarrow \infty} \|F^n\|_k^{1/n}.$$

For simplicity, when $k = \mathbb{C}$, we drop k in the notation and denote the above quantities using $\|\cdot\|$, E , Λ , and R respectively. If k is understood, sometimes we will use the subscript v for $v \in V_k$, such as Λ_v , E_v and R_v , instead of writing subscript k_v .

With the above definition, we can reformulate the normalized height for a finite set $F \subset M_d(k)$ as follows (see [6, Section 2.2]):

$$\widehat{h}(F) = \frac{1}{[k : Q]} \sum_{v \in V_K} n_v \log^+ R_v(F)$$

We will often use two basic properties that follow directly from the definition:

- (1) $\widehat{h}(F^n) = n\widehat{h}(F)$, and
- (2) $\widehat{h}(F') \leq \widehat{h}(F)$ for any subset $F' \subset F$, especially when F' consists of a single matrix $A \in F$, in which case we simply write $\widehat{h}(A)$ instead of $\widehat{h}(\{A\})$.

We will also use Lemma 2.4 below in our estimates, which is based on the following lemma of Breuillard.

Lemma 2.3 ([6, Proposition 2.7]). $\Lambda_k(F) \leq R_k(F)$.

Lemma 2.4. Let $|\cdot|_v$ be a non-archimedean place on a field K and equip $M_d(K)$ with the operator norm $\|\cdot\|_v$ induced by the norm $\|x\|_v := \max_i |x_i|_v$ on K^d . Then for any $A \in M_d(K)$ we have

$$|\mathrm{Tr} A|_v \leq R_v(A)$$

Proof. Let L be a finite extension of K , such that all the eigenvalues $\lambda_1, \dots, \lambda_d$ of A belong to L . There is a unique completion $|\cdot|_w$ extending $|\cdot|_v$. Therefore $\mathrm{Tr}(A) = \lambda_1 + \dots + \lambda_d$ and we have $|\mathrm{Tr}(A)|_v \leq \max_i |\lambda_i|_w = \Lambda_w(A)$. By Lemma 2.3, we have that $\Lambda_w(A) \leq R_w(A)$ and it is easily checked that $R_v(A) = R_w(A)$. \square

2.2. Almost laws. Given an element w in a free group $\mathbb{F}_n = \langle x_1, \dots, x_n \rangle$ of rank n , there is a natural *word map* associated to any group G

$$w: \prod_n G \rightarrow G,$$

defined as follows: Express w as a reduced word with alphabet $\{x_1^{\pm 1}, \dots, x_n^{\pm 1}\}$, and then for any $(g_1, \dots, g_n) \in \prod_n G$, substitute each x_i by g_i and x_i^{-1} by g_i^{-1} . For example, if $w = [x_1, x_2] = x_1 x_2 x_1^{-1} x_2^{-1} \in \mathbb{F}_2$, then $w(A, B) = [A, B]$.

Definition 2.5. For a group G , a *law* is a nontrivial element $w \in \mathbb{F}_n$ such that the image of w_G is the identity element 1_G . Given $\epsilon > 0$ and a metric d on G , an ϵ -almost law is a nontrivial element $w \in \mathbb{F}_n$ such that the image of G lies in an ϵ -neighborhood of 1_G .

For instance, the word $w = [x_1, x_2] \in \mathbb{F}_2$ is a law in a group G if and only if G is abelian. In general, groups obeying a law have rather special properties, for instance they contain no nonabelian free subgroups, and the stable commutator length vanishes [9]. Our proof of Theorem 1.1 relies on the following result due to A. Thom, which has also been attributed to E. Lindstrauss; see [1].

Theorem 2.6 (A. Thom [13]). *Let G be a compact Lie group and d_G a bi-invariant metric in G . For every $\epsilon > 0$, there exists an ϵ -almost law $w_\epsilon \in \mathbb{F}_2$ on G , that is, for all $A, B \in G$ we have*

$$d_G(w_\epsilon(A, B), 1_G) < \epsilon.$$

In $\mathrm{GL}_d(\mathbb{C})$, an almost law on the compact subgroup $\mathrm{U}(d)$ extends to a neighborhood. In below we denote the identity matrix as I_d , and let $d_{\mathrm{GL}_d(\mathbb{C})}(X, Y) := \|X - Y\|$, where $\|A\|$ is the operator norm with respect to the Euclidean metric for any $A \in M_d(\mathbb{C})$. Note that the restriction of $d_{\mathrm{GL}_d(\mathbb{C})}$ to $\mathrm{U}(d)$ is bi-invariant.

Corollary 2.7. *For every $d > 0$ and $\epsilon \in (0, 1)$, there exists a nontrivial element $w \in \mathbb{F}_2$ and $\delta = \delta(d, \epsilon) > 0$ such that for any $A, B \in \mathrm{GL}_d(\mathbb{C})$ satisfying $\|A\|, \|A^{-1}\|, \|B\|, \|B^{-1}\| < e^\delta$ we have*

$$d_{\mathrm{GL}_d(\mathbb{C})}(w(A, B), I_d) < \epsilon.$$

Moreover, w can be taken as any $\frac{\epsilon}{2}$ -almost law on $\mathrm{U}(d)$, and $\delta = \frac{\epsilon}{8|w|}$.

Proof. Let $w = w_{\epsilon/2}$ be an $\frac{\epsilon}{2}$ -almost law as in Theorem 2.6 for $\mathrm{U}(d)$ with respect to the restricted metric. Then for any $A, B \in \mathrm{GL}_d(\mathbb{C})$, by the

singular value decomposition we have $A = P_A \Lambda_A Q_A$ and $B = P_B \Lambda_B Q_B$ where $P_A, Q_A, P_B, Q_B \in \mathrm{U}(d)$ and Λ_A, Λ_B are positive diagonal matrices. If $\|A\|, \|A^{-1}\|, \|B\|, \|B^{-1}\| < e^\delta$ for some $\delta > 0$, then all diagonal entries of Λ_A, Λ_B lie in $(e^{-\delta}, e^\delta)$.

Let $A' = P_A Q_A$ and $B' = P_B Q_B$, which lie in $\mathrm{U}(d)$. Note that $\|A - A'\| = \|\Lambda_A - I_d\| \leq e^\delta - 1$ and $\|A^{-1} - A'^{-1}\| = \|\Lambda_A^{-1} - I_d\| \leq e^\delta - 1$, and similarly for B . By inserting intermediate words replacing one $A^{\pm 1}$ (resp. $B^{\pm 1}$) by $A'^{\pm 1}$ (resp. $B'^{\pm 1}$) at a time in the word $w_{\epsilon/2}(A, B)$, we obtain from the triangle inequality that

$$\|w_{\epsilon/2}(A, B) - w_{\epsilon/2}(A', B')\| \leq |w_{\epsilon/2}| \cdot e^{\delta(|w_{\epsilon/2}|-1)}(e^\delta - 1).$$

For $\delta = \frac{\epsilon}{8|w_{\epsilon/2}|} < 1$, we have $e^{\delta(|w_{\epsilon/2}|-1)} < e^{\epsilon/8} < 2$ and $e^\delta - 1 < 2\delta = \frac{\epsilon}{4|w_{\epsilon/2}|}$. Hence

$$\|w_{\epsilon/2}(A, B) - w_{\epsilon/2}(A', B')\| \leq |w_{\epsilon/2}| e^{\delta(|w_{\epsilon/2}|-1)}(e^\delta - 1) \leq \frac{\epsilon}{4} \cdot e^{\frac{\epsilon}{8}} \leq \frac{\epsilon}{2},$$

and

$$\|w_{\epsilon/2}(A, B) - I_d\| \leq \|w_{\epsilon/2}(A, B) - w_{\epsilon/2}(A', B')\| + \|w_{\epsilon/2}(A', B') - I_d\| \leq \epsilon$$

using the almost law. \square

Remark 2.8. To calculate explicitly the constant ϵ_d in the main theorem, one needs to compute $|w_{\epsilon/2}|$.

3. PROOF OF THEOREM 1.1

We need to prove the uniform lower bound $\widehat{h}(F) \geq \epsilon_d$ whenever $F \subset \mathrm{GL}_d(\overline{\mathbb{Q}})$ generates a group that is not virtually solvable.

To make use of this assumption on F , we need the following lemma, which relies on [10, Proposition 3.2] or [6, Lemma 4.2].

Lemma 3.1. *Given any non-trivial word $w \in \mathbb{F}_2$, there is some n_w (only depending on w and d) such that for any set $F \subset \mathrm{GL}_d(\mathbb{C})$ generating a non virtually solvable group, there exists $A, B \in F^{n_w}$ with $\mathrm{Tr}(w(A, B) - I_d) \neq 0$.*

Proof. Let Γ be the group generated by F in $\mathrm{GL}_d(\mathbb{C})$ and H be the Zariski closure of Γ . We assumed that Γ is not virtually solvable, so H is not virtually solvable. We first show that there exists $X, Y \in \Gamma$ such that $\mathrm{Tr}(w(X, Y) - I_d) \neq 0$.

As H is an algebraic group defined over \mathbb{C} , we have the Levi decomposition $H = S \ltimes U$, where U is the unipotent radical of H and S is a reductive Levi subgroup of H . Furthermore, we have a semisimple algebraic group $L = [S, S]$ so that S can be written as an almost direct product of L and the central torus T , i.e. $S = L \cdot T$ and $|L \cap T| < \infty$. Let L^0 be the connected component of identity in L .

Assume that $\mathrm{Tr}(w(X, Y) - I_d) = 0$ for all $X, Y \in \Gamma$. We claim that L^0 is trivial. Indeed, by Borel's theorem [4], the restriction of the word map to L^0 , $w: L^0 \times L^0 \rightarrow L^0$ is dominant, i.e. the image is Zariski dense in L^0 .

As $R = \{X \in H : \mathrm{Tr}(X) = d\}$ is a Zariski closed subset of H , the image of the word map w and hence L^0 are contained in R . It is easy to see that if a matrix X satisfies $\mathrm{Tr}(X^m) = d$ for all m then X is a unipotent element. This implies that every element in L^0 is unipotent so it must be trivial as L^0 is semisimple. Therefore, H is virtually solvable, as virtually it is an extension of the solvable group U by the abelian group T . This contradicts our assumption. Hence there are $X, Y \in \Gamma$ such that $\mathrm{Tr}(w(X, Y) - I_d) \neq 0$.

For the rest of proof, we think of $\mathrm{GL}_d(\mathbb{C}) \times \mathrm{GL}_d(\mathbb{C})$ as a subgroup in $\mathrm{GL}_{2d}(\mathbb{C})$ diagonally. Let H' be the Zariski closure of $\Gamma \times \Gamma$ in $\mathrm{GL}_{2d}(\mathbb{C})$. Then the subset

$$\mathcal{X} = \{(A, B) \in \mathrm{GL}_d(\mathbb{C}) \times \mathrm{GL}_d(\mathbb{C}) : \mathrm{Tr}(w(A, B) - I_d) = 0\} \cap H' \subset \mathrm{GL}_{2d}(\mathbb{C})$$

is Zariski closed in H' . As we saw above, \mathcal{X} is a proper Zariski closed subset in H' . Using the fact that $\Gamma \times \Gamma$ is generated by $F \times F$, [10, Proposition 3.2] or [6, Lemma 4.2] says that there exists $n_w \geq 1$ only depending on d and w such that we have

$$\{(A, B) \in \Gamma \times \Gamma : A, B \in F^{n_w} \subset \Gamma\} \not\subset \mathcal{X}$$

as desired. \square

Let K be a number field so that $F \subset \mathrm{GL}_d(K)$. Let $k = [K : \mathbb{Q}]$ and let $\sigma_1, \sigma_2, \dots, \sigma_k$ be all the embeddings of K in \mathbb{C} . Fix any $\epsilon \in (0, 1)$, choose an $\frac{\epsilon}{2}$ -almost law $w = w_{\epsilon/2}$ on $\mathrm{U}(d)$ and let $\delta = \frac{\epsilon}{8|w|}$ as in Corollary 2.7. For $w = w(x, y) \in \mathbb{F}_2 = \langle x, y \rangle$, let $w' = w([x, y], [x^{-1}, y]) \in \mathbb{F}_2$. Note that w' is still nontrivial since $[x, y]$ and $[x^{-1}, y]$ generate a free subgroup of \mathbb{F}_2 . Denote the word length of w by $|w|$.

For technical reasons later, we need the following improvement of Lemma 3.1 to ensure that $A, B \in \mathrm{SL}_d(\mathbb{C})$.

Lemma 3.2. *In the above setting, there is $n = n_w$ only depending on w and d such that for any finite set $F \subset \mathrm{GL}_d(\mathbb{C})$ generating a subgroup that is not virtually solvable, there exists $A, B \in F^{n_w} \cap \mathrm{SL}_d(\mathbb{C})$ with $\mathrm{Tr}(w(A, B) - I_d) \neq 0$.*

Proof. Applying Lemma 3.1 to w' we described above, we obtain some n' (relying only on w and d) and $A_1, B_1 \in F^{n'}$ such that $\mathrm{Tr}(w(A_1, B_1) - I_d) \neq 0$. Let $n = n_w := 4n'$, $A = [A_1, B_1]$ and $B = [A_1^{-1}, B_1]$. Then $A, B \in F^n \cap \mathrm{SL}_d(\mathbb{C})$, and $w(A, B) = w'(A_1, B_1)$ by definition. Hence $\mathrm{Tr}(w(A, B) - I_d) \neq 0$. \square

Let $n = n_w$ and $A, B \in F^{n_w} \cap \mathrm{SL}_d(\mathbb{C})$ be as in Lemma 3.2.

Consider the following quantity:

$$(2) \quad Q := \prod_{i=1}^k (\mathrm{Tr}(w(A_i, B_i) - I_d)),$$

where $A_i = \sigma_i(A)$ and $B_i = \sigma_i(B)$.

This is a nonzero rational number since $\text{Tr}(w(A, B) - \text{Id}) \neq 0$. Let

$$\epsilon_2 = \frac{\log \frac{1}{\epsilon}}{\log \frac{2d}{\epsilon} + \frac{|w|\delta^2}{16d \log \frac{1}{\epsilon}}}, \quad \text{and} \quad \epsilon_1 = \frac{1}{2} \left(\log \frac{1}{\epsilon} - \epsilon_2 \log \frac{2d}{\epsilon} \right),$$

where $\delta = \frac{\epsilon}{8|w|}$ as in Corollary 2.7 and $0 < c < 1$ is the constant (only depending on d) from Proposition 3.5 below, which can be chosen as $c = \frac{1}{2d}$. Note that $\epsilon_2 < \log \frac{1}{\epsilon} / \log \frac{2d}{\epsilon} < 1$ and thus $\epsilon_1 > 0$. Let

$$(3) \quad \epsilon_d := \frac{\epsilon_2 \delta^2}{32nd \log \frac{1}{c}} = \frac{\delta^2 \log \frac{1}{\epsilon}}{32nd \log \frac{2d}{\epsilon} \log \frac{1}{c} + 2n|w|\delta^2},$$

which is at least at the order of $\frac{1}{n(d^2|w|^2+|w|)}$ as $d \rightarrow \infty$ by setting $\epsilon \in (0, 1)$ independent of d . The constants ϵ_1 and ϵ_2 are chosen so that

$$\epsilon_d = \frac{\epsilon_2 \delta^2}{32nd \log \frac{1}{c}} = \frac{-\epsilon_1 + (1 - \epsilon_2) \log \frac{1}{\epsilon} - \epsilon_2 \log 2d}{n|w|} = \frac{\epsilon_1}{n|w|},$$

which are the lower bounds of the normalized height in the analysis below.

We consider the two possibilities in the following two subsections.

3.1. Case 1: $|Q| \geq e^{-\epsilon_1 k}$. In this case, we will use the estimate

$$(4) \quad \widehat{h}(F) = \frac{1}{k} \sum_{v \in V_K} n_v \log^+ R_v(F) \geq \frac{1}{k} \sum_{i=1}^k \log^+ R_i(F),$$

where $R_i(F) = R(\sigma_i(F))$ and we simply ignore the non-archimedean places.

Partition the index set $I := \{1, 2, \dots, k\}$ as $I = I_S \sqcup I_M \sqcup I_L$, where

$$I_S := \{i : |\text{Tr}(w(A_i, B_i) - I_d)| < \epsilon\}, \quad I_L := \{i : |\text{Tr}(w(A_i, B_i) - I_d)| > 2d\},$$

and $I_M = I \setminus (I_S \sqcup I_L)$. Note that $I_S \cap I_L = \emptyset$ since $\epsilon < 1$.

We further consider two subcases depending on the size of I_S .

3.1.1. Case 1a: $|I_S| > (1 - \epsilon_2)k$. In this case, we have

$$\prod_{i \notin I_S} |\text{Tr}(w(A_i, B_i) - I_d)| = \frac{|Q|}{\left| \prod_{i \in I_S} \text{Tr}(w(A_i, B_i) - I_d) \right|} \geq e^{-\epsilon_1 k} \cdot \epsilon^{-|I_S|}.$$

Taking log on both sides, we have

$$\sum_{i \notin I_S} \log |\text{Tr}(w(A_i, B_i) - I_d)| \geq -\epsilon_1 k + |I_S| \log \frac{1}{\epsilon} \geq -\epsilon_1 k + (1 - \epsilon_2)k \log \frac{1}{\epsilon}.$$

As $|\text{Tr}(w(A_i, B_i) - I_d)| \leq 2d$ for all $i \in I_M$, it follows that

$$(5) \quad \begin{aligned} \sum_{i \in I_L} \log |\text{Tr}(w(A_i, B_i) - I_d)| &\geq \sum_{i \notin I_S} \log |\text{Tr}(w(A_i, B_i) - I_d)| - |I_M| \log 2d \\ &\geq -\epsilon_1 k + (1 - \epsilon_2)k \log \frac{1}{\epsilon} - |I_M| \log 2d. \end{aligned}$$

Lemma 3.3. *For any $X \in \mathrm{GL}_d(\mathbb{C})$, if $|\mathrm{Tr}(X - I_d)| > d$, then the spectral radius $\Lambda(X) \geq \frac{1}{d}|\mathrm{Tr}(X - I_d)| - 1$. Moreover, if $|\mathrm{Tr}(X - I_d)| > 2d$, then $\Lambda(X) \geq \frac{1}{2d}|\mathrm{Tr}(X - I_d)|$.*

Proof. Let $r = \frac{1}{d}|\mathrm{Tr}(X - I_d)|$ and let $\lambda_1, \dots, \lambda_d \in \mathbb{C}$ be the eigenvalues of X . Then for the average $\bar{\lambda} = \frac{1}{d} \sum_{j=1}^d \lambda_j$ we have $r = |\bar{\lambda} - 1|$.

It follows that some λ_i lies outside the open disk D of radius r around $1 \in \mathbb{C}$, since otherwise their average $\bar{\lambda}$ lies in D by convexity, contradicting $r = |\bar{\lambda} - 1|$.

Since $r > 1$ by our assumption, the disk D contains the open disk B of radius $r - 1$ around $0 \in \mathbb{C}$. Thus $\lambda_i \notin B$ and $\Lambda(X) \geq |\lambda_i| \geq r - 1$.

In the case $r > 2$, we further have $\Lambda(X) \geq r - 1 \geq r - \frac{r}{2} = \frac{r}{2}$. \square

Applying Lemma 3.3 to the left-hand side of Equation (5) we obtain

$$\begin{aligned} \sum_{i \in I_L} \log(2d\Lambda(w(A_i, B_i))) &\geq -\epsilon_1 k + (1 - \epsilon_2)k \log \frac{1}{\epsilon} - |I_M| \log 2d, \\ \sum_{i \in I_L} \log(\Lambda(w(A_i, B_i))) &\geq -\epsilon_1 k + (1 - \epsilon_2)k \log \frac{1}{\epsilon} - (|I_M| + |I_L|) \log 2d \\ &> -\epsilon_1 k + (1 - \epsilon_2)k \log \frac{1}{\epsilon} - \epsilon_2 k \log 2d \end{aligned}$$

since $|I_M| + |I_L| = |I| - |I_S| < \epsilon_2 k$.

Combining this with Equation (4) and Lemma 2.3, as $w(A, B) \in F^{n|w|}$, we conclude

$$\begin{aligned} n|w| \cdot \widehat{h}(F) &= \widehat{h}(F^{n|w|}) \geq \frac{1}{k} \sum_{i \in I_L} \log(R_i(w(A, B))) \\ &\geq \frac{1}{k} \sum_{i \in I_L} \log(\Lambda(w(A_i, B_i))) \\ &\geq -\epsilon_1 + (1 - \epsilon_2) \log \frac{1}{\epsilon} - \epsilon_2 \log 2d \\ &= n|w|\epsilon_d. \end{aligned}$$

Thus $\widehat{h}(F) \geq \epsilon_d$ as desired in this situation.

3.1.2. Case 1b: $|I_S| \leq (1 - \epsilon_2)k$. Recall that for any $i \notin I_S$, we have $|\mathrm{Tr}(w(A_i, B_i)) - I_d| \geq \epsilon$. Since trace is conjugate-invariant, we know that $|\mathrm{Tr}(w(CA_iC^{-1}, CB_iC^{-1})) - I_d| \geq \epsilon$ for all $C \in \mathrm{GL}_d(\mathbb{C})$. Thus by Corollary 2.7, for any $i \notin I_S$ and any $C \in \mathrm{GL}_d(\mathbb{C})$, at least one of the four matrices $CA_i^{\pm 1}C^{-1}, CB_i^{\pm 1}C^{-1}$ has norm no less than e^δ . Thus we have $E(T_i) \geq e^\delta$ for $T_i := \{A_i^{\pm 1}, B_i^{\pm 1}\}$.

In particular, this implies that for one element among $\{A^{\pm 1}, B^{\pm 1}\}$, let's say A , we have $\|A_i\| \geq e^\delta$ for $\frac{1}{4}\epsilon_2 k$ different i 's and that implies the lower

bound $h(F^{n_w}) \geq h(A) \geq \frac{1}{4}\epsilon_2\delta$, which implies

$$h(F) \geq \frac{\frac{1}{4}\epsilon_2\delta}{n_w}.$$

As we want to obtain a bound for the normalized height and not only for the height, we need a way to compare them. To do this we will make use of the following two propositions, which are due to Breuillard. Recall that our A, B lie in $\mathrm{SL}_d(\mathbb{C})$.

Proposition 3.4 ([6, Proposition 2.9]). *For any $M \in \mathbb{Z}_+$ and a finite subset $F \subset \mathrm{SL}_d(\mathbb{C})$, we have*

$$E(F^M) \geq E(F)\sqrt{\frac{M}{4d}}$$

Proposition 3.5 ([6, Lemma 2.1(b)]). *There are uniform constants $c = c(d)$ and $N(d)$ such that for any finite subset $F \subset \mathrm{GL}_d(\mathbb{C})$ there is $q \in [1, N(d)]$ with*

$$\Lambda(F^{qM}) \geq c^q E(F^M)^q,$$

The latter proposition can be deduced from an inequality of Bochi [3, Theorem B], which was also recently proved by Breuillard in [8] with a good choice of $c = c(d)$ (at the cost of increasing $N(d)$); See [8, Theorem 5]. The inequality of Breuillard together with [8, Lemma 1] implies that one can take $c = \frac{1}{2d}$.

These propositions imply that for every $i \notin I_S$, there is some q with

$$\Lambda(T_i^{qM}) \geq c^q E(T_i^M)^q \geq c^q E(T_i)^q \sqrt{\frac{M}{4d}} \geq c^q e^{q\delta} \sqrt{\frac{M}{4d}}.$$

Note that for $T := \{A^{\pm 1}, B^{\pm 1}\}$, we have $T \subset F^n$ and thus $T_i^{qM} \subset (\sigma_i F)^{nqM}$. Therefore, using the estimate above, we obtain

$$R_i(F)^{nqM} = R_i(F^{nqM}) = R((\sigma_i F)^{nqM}) \geq R(T_i^{qM}) \geq \Lambda(T_i^{qM}) \geq c^q e^{q\delta} \sqrt{\frac{M}{4d}}.$$

That is,

$$\log R_i(F) \geq \frac{1}{nM} \left(\log c + \delta \sqrt{\frac{M}{4d}} \right).$$

Here $\log(c) < 0$, so the right hand side is maximized to $\frac{\delta^2}{16nd \log(1/c)}$ when $M = (16d \log^2 c)/\delta^2$. As M is an integer, we should take $M = \lfloor (16d \log^2 c)/\delta^2 \rfloor$ or $\lceil (16d \log^2 c)/\delta^2 \rceil$. Since $(16d \log^2 c)/\delta^2$ is sufficiently large, in either case we get

$$\log R_i(F) \geq \frac{\delta^2}{32nd \log \frac{1}{c}}.$$

Hence by Equation (4), we have

$$\hat{h}(F) \geq \frac{1}{k} \sum_{i \notin I_S} \log^+ R_i(F) \geq \frac{\epsilon_2 \delta^2}{32nd \log \frac{1}{c}} = \epsilon_d.$$

3.2. Case 2: $|Q| < e^{-\epsilon_1 k}$. In this case, for $\alpha := \mathrm{Tr}(w(A, B) - I_d)$, we can apply the product formula Theorem 2.1 so that

$$\prod_{v \in V_K^f} |\alpha|_v^{n_v} = \frac{1}{|Q|} > e^{\epsilon_1 k},$$

where V_K^f denotes the non-archimedean places of K .

Since $|\cdot|_v$ is an ultrametric for all $v \in V_K^f$, by Lemma 2.4 we have

$$|\alpha|_v \leq \max\{|\mathrm{Tr}(w(A, B))|_v, |\mathrm{Tr}(I_d)|_v\} \leq \max\{R_v(w(A, B)), 1\}.$$

Hence for all $v \in V_K^f$ we have

$$\log |\alpha|_v \leq \log^+ R_v(w(A, B))$$

Therefore, this inequality and the product formula together imply

$$\begin{aligned} \widehat{h}(F) &= \frac{1}{n|w|} \widehat{h}(F^{n|w|}) \geq \frac{1}{n|w|} \widehat{h}(w(A, B)) \\ &\geq \frac{1}{n|w|k} \sum_{v \in V_K^f} \log^+ R_v(w(A, B)) \\ &\geq \frac{1}{n|w|k} \sum_{v \in V_K^f} \log |\alpha|_v \\ &\geq \frac{1}{n|w|k} (\epsilon_1 k) \\ &= \frac{\epsilon_1}{n|w|} \\ &= \epsilon_d. \end{aligned}$$

4. REMARKS ABOUT EXPLICIT ESTIMATES OF THE HEIGHT GAP ϵ_d

One can construct examples showing that the height gap $\epsilon_d \leq \frac{c}{d}$ for some $c > 0$ independent of d . A natural question is to determine the actual order of ϵ_d and Breuillard has asked the following:

Question 4.1. *Is $\epsilon_d \geq \frac{1}{cd^c}$ for some $c > 0$?*

We will explain how our method might lead to obtain some explicit bounds for this constant.

From equation (3), we have that

$$\epsilon_d \geq \frac{\delta^2 \log \frac{1}{\epsilon}}{32n_w d \log \frac{2d}{\epsilon} \log \frac{1}{c} + 2n_w |w| \delta^2},$$

where c is the constant appearing in Proposition 3.5 and $\delta = \frac{\epsilon}{8|w|}$. Recently Breuillard proved that c can be taken to $\frac{1}{2d}$ by [8, Theorem 5 and Lemma

1]. Therefore by taking $\epsilon = 1/4$, we see that ϵ_d is at least at the order of

$$\frac{1}{n_w(d^2|w|^2 + |w|)},$$

where $|w|$ is the word length of a $\frac{1}{4}$ -almost law w on $U(d)$ and the constant n_w comes from the escape of the hypersurface \mathcal{X} defined by

$$\text{Tr}(w(X, Y) - \text{Id}) = 0$$

as in Lemma 3.1.

One can obtain a bound of the order of 10^{10^d} for $|w|$ by considering the almost laws described by Thom in [13]. It is nonetheless quite likely that a much shorter almost law w exists. Thom and Breuillard pointed out to us the fact that Kozma and Thom showed in [12] that for the symmetric group S_d (which in some ways behave similarly to $SU(d)$ when d is large), there exists a law of order $e^{C \log^4(d) \log \log(d)}$, which assuming Babai's conjecture could be improved to be of the order $e^{C \log(d) \log \log(d)}$, which is quite close to be polynomial.

The constant n_w when computed from the generalized Bezout's Theorem as in [10] seems to be quite large. It was suggested by Breuillard that there seems to be another way of estimating n_w by considering an appropriate finite quotient of the group generated by F (for example by moding out a prime ideal of the ring where F is defined), and then showing that in this finite quotient one can escape from the hypersurface \mathcal{X} quickly. The advantage is that there are various results about the diameter of simple groups. Michael Larsen suggested the use of a strong approximation theorem by Weisfeiler [14] to find the appropriate quotient.

To implement this idea, one must make sure the reduction of \mathcal{X} to this finite group of Lie type is a proper subset. The dimension of the variety \mathcal{X} is bounded by $d|w|$ and so the reduction of \mathcal{X} can be proved to be a proper subset via the Schwartz–Zippel lemma, or via the Lang–Weil estimates, provided that the finite quotient is large enough (the prime ideal giving rise to the finite quotient must have covolume larger than the degree of \mathcal{X} , at least).

Assuming Babai's conjecture about the diameter of finite groups one then might expect that n_w could be taken of the order $(|d \log(|w|)|)^{O(1)}$ and using results towards Babai conjecture this can possibly be taken to be of the order $e^{(|d \log(|w|)|)^{O(1)}}$, see [2].
